

V8 -- empirical law of $\log k_t$ vs the assumed laws of TIS / IcePop / KPop (dense, 12,389,115 tokens, axis: entropy)

(a) conditional quantile fan of $\log k_t | H$

(b) scale law: TIS/IcePop assume flat; KPop assumes $\propto (1 - p_t)$

(c) shape: near scale-family, non-Gaussian tails

(d) conditional identity check (y_t -free axis)

(e) outlier-branch asymmetry vs IcePop's symmetric mixture

(f) IcePop $\text{Exp}(\lambda)$ branch: straight iff exponential
